

Configure switch port access delay

Overview

To configure the LAG, click on the furthest away switch in the list of devices, then click on 'Ports' Next, click on 'Port Management', which is the new way to manage switch port configurations in UniFi version 7. Port Settings — You can configure the Up or Down state of the port for a specific period. This helps simplify the configuration of the WLC interface ports, increase available bandwidth between the wireless and wired network. Portfast is used to avoid the delay that happens in the spanning tree when connecting a new device to the network. When port fast is enabled on an interface the interface whenever it detects a protocol up the event, the port skips the listening and learning spanning tree states and goes straight to. On the Port settings page, you can configure and monitor individual switch ports, including basic settings, LAG ports with LACP support, advanced features, port mirroring, loopback detection, PoE management with keepalive functionality, and STP configuration for preventing network loops. The basic. When a member port fails, its traffic is automatically switched to other member ports.
