

Distribution box spans cabinets

Overview

The core differences between distribution cabinets and distribution boxes lie in their size, capacity, installation method, and application scenarios. You can simply understand them as follows: a "cabinet" is large and freestanding; a "box" is small and mounted on or embedded in a wall. Distribution boxes are mainly used for controlling and distributing power to electrical equipment, and for protecting circuits against overload, short circuits, and leakage. Distribution boxes are installed in various places, such as schools, government offices, hospitals, factories, workshops, and so on. A distribution box is a low-voltage electrical enclosure that receives incoming power and distributes it safely to multiple outgoing circuits through protective and switching devices such as MCBs, RCDs, RCBOs, fuses, isolators, busbars, neutral bars, earth bars, and surge protective devices. Distribution boxes and cabinets are complete sets of equipment. The hub distributes electrical power from a single input source to various circuits throughout a building.
