

Fiber optic bundles are formed into optical cables

Overview

Fiber optic bundles consist of multiple optical fibers grouped together to transmit light signals simultaneously. These bundles are integral to various applications, including imaging systems, illumination, spectroscopy, sensors, and high-speed data transmission across diverse. Fiber bundles may have different input and output shapes. The shapes of the input and output interface do not necessarily have to be identical. When this multiplicity of fibers is randomly gathered, it is usually collected in a jacket (buffer, sheathing, housing) and held together at each end with epoxy to form an output or. An optical fiber bundle comprises a number of individual optical fibers bundled together to form a fiber optic bundle (see Figure 1). They can be bare or coated fibers and come bundled within an outer. Fiber optic bundle is divided into two types in the industry: rigid fiber optic bundles and flexible fiber optic bundles.

Optical fiber is used as a medium for telecommunication and computer networking because it is flexible and can be bundled as cables. It is especially advantageous for long-distance communications, because infrared light propagates through the fiber with much lower attenuation compared to electricity in electrical cables. This allows long distances to be spanned with few repeaters.
