

How is the optical module PE

Overview

An optical module is a typically hot-pluggable optical transceiver used in high-bandwidth data communications applications. Optical modules typically have an electrical interface on the side that connects to the inside of the system and an optical interface on the side that connects to the outside world through a fiber optic cable. The form factor and electrical interface are often specified by an interested group using a (MSA). Optical modules can either plug into a front panel.

AI Overview

The PE performance of an optical module reflects its ability to convert electrical signals into optical signals and back efficiently, measured by parameters like average optical power and extinction ratio. Working Principle An optical module operates at the physical layer of the OSI model, serving as a photoelectric converter in fiber-optic communication systems. It converts electrical signals into optical signals via a Transmitter Optical Sub-Assembly (TOSA), typically using a laser diode (LD) or LED, and converts received optical signals back into electrical signals using a Receiving Optical Sub-Assembly (ROSA) with a photodetector diode. The internal driver chips modulate the light according to the input electrical signal, and preamplifiers ensure the output electrical signal maintains the correct bit rate. Key PE Performance Indicators Average Optical Power This measures the intensity of light emitted by the transmitter under normal operation. It is influenced by the proportion of "1"s in the transmitted data. When transmitting a pseudo-random sequence with roughly equal "1"s and "0"s, the measured power represents the average optical power, expressed in W, mW, or dBm. Extinction Ratio The extinction ratio quantifies the module's ability to distinguish between logical "1" and "0" signals. It is the ratio of the average optical power when transmitting all "1"s to the power when transmitting all "0"s, measured...
