

KVM switcher is a link

Various specifications optional

AI Overview

A KVM switcher is a hardware device that allows one keyboard, monitor, and mouse to control multiple computers, not a web link. A KVM switch (Keyboard, Video, Mouse) is a physical device that enables a user to control multiple computers or servers from a single set of peripherals, including a keyboard, monitor, and mouse. It is commonly used in data centers, server rooms, and IT environments to reduce clutter and improve efficiency by eliminating the need for multiple keyboards and monitors. How a KVM Switch Works The KVM switch connects each computer to the switch using cables (USB, VGA, HDMI, or DVI), while the keyboard, monitor, and mouse are connected to the switch itself. Users can switch control between computers using: Physical buttons on the KVM switch Hotkey combinations from the keyboard On-Screen Display (OSD) menus in some models Advanced KVM switches may also support audio, USB peripherals, multi-screen setups, and remote access over IP networks, allowing management of servers from anywhere with an internet connection. Types of KVM Switches Local KVM switches: For nearby computers, providing direct physical access. IP/Digital KVM switches: Allow remote access via a web browser or network, often supporting cascaded configurations to control dozens of servers. Multi-viewer KVMs: Display multiple desktops on a single monitor for high-performance environments. In summary, a KVM switcher is a hardware solution for centralized control of multiple computers, not a clickable link. It simplifies workstation management, reduces hardware costs, and enhances productivity in environments where multiple systems need to be accessed efficiently.
