

Principle of trip light in relay protection device

Overview

Relay trip outputs usually depend on a reliable control power source, often a station battery or DC control system. When the relay asserts trip, its output contact or logic output energizes a trip coil, lockout relay, or breaker control circuit. The protection relay tripping circuit refers to the critical electrical control loop that executes trip/close commands from protective relays to circuit breakers, ensuring rapid fault isolation in power systems. Essential. A protective relay is an intelligent electrical device designed to detect faults in power systems and initiate corrective actions such as tripping a circuit breaker. In this article we will discuss, the working, function, and significance of the Master Trip Relay, also known as the 86 relay. The power required by the trip coil of the CB may range from 50 W for a small distribution CB to 3000 W for a large EHV CB. Where such appreciable current-carrying capacity is required, interposing contactor type elements will.
