

What is a gigabit single-mode optical module

AI Overview

A Gigabit Single-Mode Optical Module converts electrical signals from network devices into optical signals for long-distance fiber transmission and vice versa, enabling 1Gbps Ethernet connectivity over single-mode fiber. Core Function A Gigabit Single-Mode Optical Module, often implemented as a 1G SFP transceiver, serves as a hot-pluggable interface between network equipment (like switches or routers) and single-mode fiber optic cables. Its primary function is to convert electrical signals from the host device into optical signals for transmission over fiber and to convert incoming optical signals back into electrical signals for the device. This enables seamless 1Gbps full-duplex communication while maintaining signal integrity and Ethernet compliance. Transmission Characteristics Single-mode optical modules are designed for long-distance communication, typically ranging from 10 km to over 120 km, depending on the module specifications and optical power. They operate at specific wavelengths, commonly around 1310 nm, which minimizes signal dispersion and allows the optical signal to travel farther than multimode fiber. The module's laser diode generates the optical signal, while a photodiode receiver detects incoming light and converts it back to electrical form. Key Technical Features Hot-pluggable design: Can be inserted or removed without powering down the network device, simplifying maintenance and upgrades. Signal conversion: Translates electrical signals to optical signals and vice versa, ensuring compatibility with standard Gigabit Ethernet devices. Optical power and sensitivity: Determines the maximum transmission distance and reliability; transmit power is the output of the laser, and receive sensitivity is the minimum detectable signal for error-free communication. Interface type: Single-mode SFP modules typically use LC connecto...
